

# 12V, Ultra-Low-IQ, Low-Dropout Linear Regulators with POK

MAX8880/MAX8881

## General Description

The MAX8880/MAX8881 are ultra-low supply current, low-dropout linear regulators, capable of delivering up to 200mA. They are designed for battery-powered applications where reverse battery protection and long battery life are critical.

These regulators' low 3.5µA supply current extends battery life in applications with long standby periods. Unlike PNP-based designs, a 2Ω PMOS device maintains ultra-low supply current throughout the entire operating range and in dropout. The parts are internally protected from output short circuits, reverse battery connection, and thermal overload. An internal power-OK (POK) comparator indicates when the output is out of regulation.

The MAX8880 output is adjustable from 1.25V to 5V using an external resistor-divider. The MAX8881 provides only factory-preset output voltages of 1.8V, 2.5V, 3.3V, or 5V (see *Ordering Information*). Both devices are available in miniature 6-pin SOT23 packages.

## Applications

Smoke Detectors	PDA's
Battery-Powered Alarms	Handy Terminals
Remote Transmitters	CMOS Backup Power
Smart Battery Packs	Real-Time Clocks

## Pin Configuration

## Features

- ◆ 3.5µA Supply Current at 12V
- ◆ Reverse Battery Protection
- ◆ 2.5V to 12V Input Voltage Range
- ◆ ±1.5% Output Voltage Accuracy
- ◆ 200mA max Output Current
- ◆ 2Ω PMOS Output Device
- ◆ Short-Circuit and Thermal Overload Protection
- ◆ POK Output for Out-of-Regulation Indicator
- ◆ Fixed 1.8V, 2.5V, 3.3V, and 5V (MAX8881)  
Adjustable from 1.25V to 5V (MAX8880)
- ◆ Tiny 6-Pin SOT23 Package

## Typical Operating Circuit

MAX8880/MAX8881

## Pin Description

PIN	NAME	FUNCTION
1	IN	Input Voltage. Bypass with a 1μF capacitor to GND.
2	GND	Ground
3	OUT	Output Voltage. Bypass with a 4.7μF capacitor (<0.5Ω ESR) to GND for load currents up to 200mA. For load currents up to 40mA, 1μF is acceptable.
4	FB	Feedback Set Point, 1.25V (MAX8880 only). Output sense, connect to OUT externally (MAX8881EUT_ _ only).
5	SHDN	ON/OFF Control. Regulator is ON when $V_{SHDN} > 2V$ . If unused, connect to IN. If reverse battery protection of the SHDN input is desired, connect a 100kΩ resistor in series with SHDN.
6	POK	POK Output, Open Drain. Low when OUT is out of regulation or in shutdown. Connect POK to IN through a high-value resistor for a simple error indicator.

## Detailed Description

The MAX8880/MAX8881 are low-dropout, low-quiescent current linear regulators designed primarily for battery-powered applications (Figure 1). The MAX8880 provides an adjustable output voltage from 1.25V to 5V using an external resistor-divider. The MAX8881 is available in factory preset output voltages of 1.8V, 2.5V, 3.3V, and 5V. Both devices have a +1.25V reference, error amplifier, MOSFET driver, and P-channel pass transistor (Figure 2).

### Low-Dropout Regulator

The 1.25V reference is connected to the error amplifier's inverting input. The error amplifier compares this reference with the selected feedback voltage and amplifies the difference. The MOSFET driver reads the error signal and applies the appropriate drive to the P-channel pass transistor. If the feedback voltage is lower

than the reference voltage, the pass-transistor gate is pulled lower, allowing more current to pass, increasing the output voltage. If the feedback voltage is higher than the reference voltage, the pass-transistor gate is driven higher, allowing less current to pass to the output. The output voltage is fed back through either an internal resistor voltage divider by externally connecting FB to OUT (MAX8881EUT\_ \_), or an external resistor network connected to FB (MAX8880). Additional blocks include an output current limiter, reverse battery protection, a thermal sensor, shutdown logic, and a POK comparator to indicate when the output is out of regulation (Figure 2).

### Internal P-Channel Pass Transistor

The MAX8880/MAX8881 feature a 2Ω P-channel MOSFET pass transistor. This provides advantages over similar designs using PNP pass transistors, including longer battery life. The P-channel MOSFET requires no base drive, which reduces quiescent current considerably. PNP-based regulators waste considerable current in dropout when the pass transistor saturates. They also use high base-drive currents under large loads. The MAX8880/MAX8881 do not suffer from these problems and consume only 3.5μA of supply current (see *Typical Operating Characteristics*).

### Dropout Voltage

A regulator's minimum input-output differential (or dropout voltage) determines the lowest usable supply voltage. In battery-powered systems, this determines the useful end-of-life battery voltage. Because the MAX8880/MAX8881 use a P-channel MOSFET pass transistor, their dropout voltage is  $R_{DS(ON)} (2\Omega)$  multiplied by the load current (see *Electrical Characteristics*).

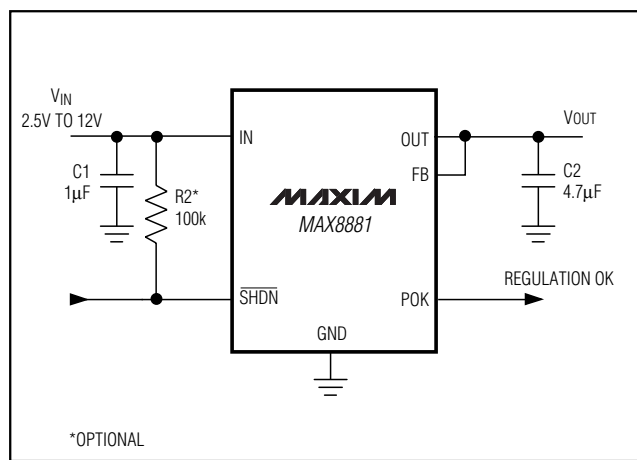

Figure 1. Standard Application Circuit

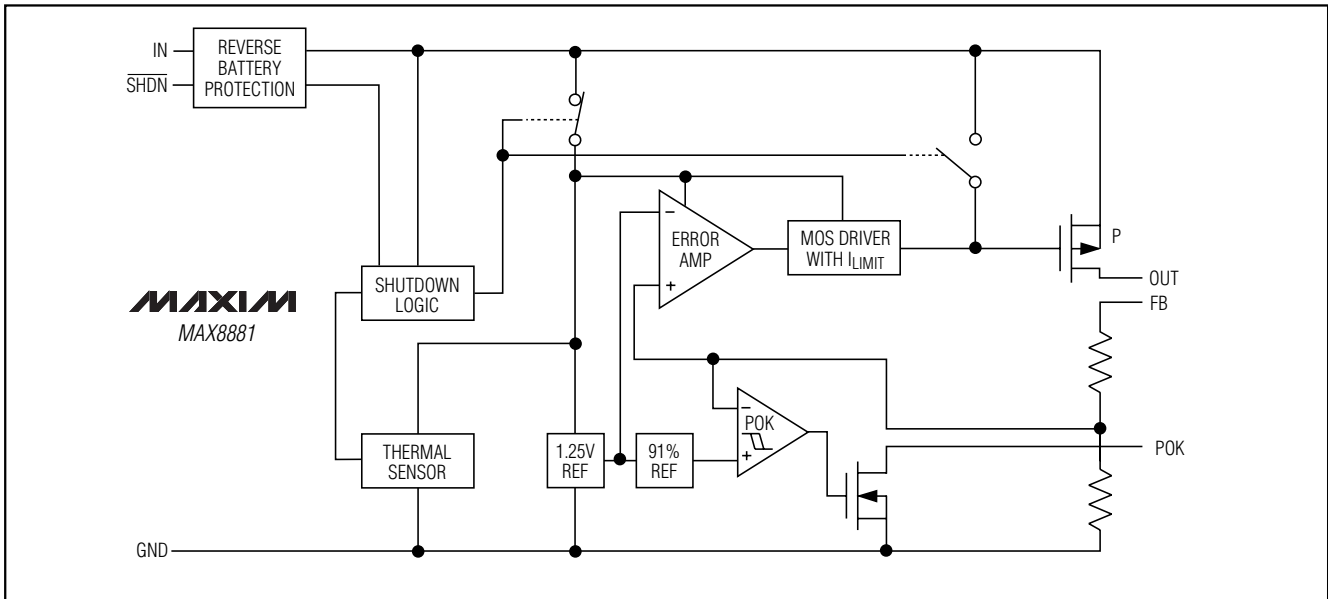

Figure 2. Functional Diagram

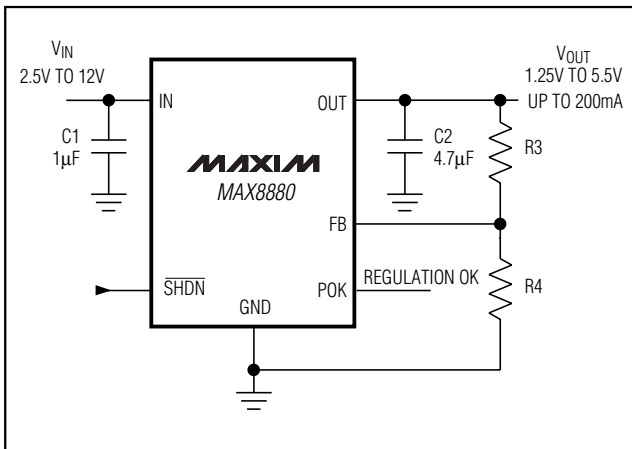

Figure 3. Adjustable Output Using External Feedback Resistors

### Reverse Battery Protection

The MAX8880/MAX8881 have a unique protection scheme that limits the reverse supply current to less than 1mA when  $V_{IN}$  is forced below ground. The circuit monitors the polarity of IN, disconnecting the internal circuitry and parasitic diodes when the battery is reversed. This feature prevents the device from electrical stress and damage when the battery is connected backwards. If reverse battery protection is needed, drive SHDN through a 100k $\Omega$  resistor.

### Current Limiting

The MAX8880/MAX8881 include a current limiter. When the output is shorted to ground, drive to the output PMOS is limited. The output can be shorted to ground without damage to the part.

### Thermal Overload Protection

Thermal overload protection limits total power dissipation in the MAX8880/MAX8881. When the internal junction temperature exceeds  $T_J = +160^\circ\text{C}$ , the thermal sensor signals the shutdown logic, turning off the pass transistor and allowing the IC to cool. The thermal sensor turns the pass transistor on again after the IC's junction temperature cools by  $15^\circ\text{C}$ , resulting in a pulsed output during continuous thermal-overload conditions.

Thermal-overload protection is designed to protect the MAX8880/MAX8881 in the event of fault conditions. For continuous operation, do not exceed the absolute maximum junction temperature rating of  $T_{J(\text{MAX})} = +150^\circ\text{C}$ .

### Operating Region and Power Dissipation

The MAX8880/MAX8881's maximum power dissipation depends on the thermal resistance of the case and circuit board, the temperature difference between the die junction and ambient air, and the rate of airflow. The power dissipation in the device is  $P = I_{\text{OUT}} (V_{\text{IN}} - V_{\text{OUT}})$ . The maximum power dissipation allowed is:

# 12V, Ultra-Low-IQ, Low-Dropout Linear Regulators with POK

$$P_{MAX} = \frac{(T_{J(MAX)} - T_A)}{(\theta_{JC} + \theta_{CA})}$$

where  $T_{J(MAX)} = +150^{\circ}\text{C}$ ,  $T_A$  is the ambient temperature,  $\theta_{JC}$  is the thermal resistance from the junction to the case ( $115^{\circ}\text{C/W}$ ), and  $\theta_{CA}$  is the thermal resistance from the case through the PC board, copper traces, and other materials to the surrounding air.

## POK Output

The open-drain POK output is useful as a simple error flag, as well as a delayed reset output. POK sinks current when the output voltage is 10% below the regulation point. Connect POK to OUT through a high-value resistor for a simple error flag indicator. Connect a capacitor in parallel with the resistor to produce a delayed POK signal (delay set by the RC time constant). POK is low during out of regulation or in shutdown and is high impedance during normal operation.

## Applications Information

### Capacitor Selection and Regulator Stability

The MAX8880/MAX8881 are designed to be stable with an output filter capacitor as low as  $1\mu\text{F}$  and an ESR as high as  $1\Omega$ . For general purposes, use a  $1\mu\text{F}$  capacitor on the device's input and a  $4.7\mu\text{F}$  capacitor on the output. Larger input capacitor values and lower ESR provide better supply-noise rejection and transient response. Use a higher value input capacitor ( $10\mu\text{F}$  may be necessary) if large, fast transients are anticipated and the device is located several inches from the power source. Use large output capacitors to improve load-transient response, stability, and power-supply rejection. Note that some ceramic dielectric materials (e.g., Z5U and Y5V) exhibit a large temperature coefficient for both capacitance and ESR, and a larger output capacitance may be needed to ensure stability at low temperatures. A  $4.7\mu\text{F}$  output capacitor with X7R or X5R dielectrics should be sufficient for stable operation over the full temperature range, with load currents up to  $200\text{mA}$ . For load currents up to  $40\text{mA}$ ,  $1\mu\text{F}$  is acceptable. A graph of the Region of Stable  $C_{OUT}$  ESR vs. Output Current is shown in the *Typical Operating Characteristics*.

### Output Voltage Selection

The MAX8881 features a preset output voltage. Internal precision feedback resistors set the MAX8881EUT18 output to  $1.8\text{V}$ , the MAX8881EUT25 output to  $2.5\text{V}$ , the MAX8881EUT33 output to  $3.3\text{V}$ , and the MAX8881EUT50

output to  $5\text{V}$ . Connect the MAX8881's FB to OUT for proper operation.

The MAX8880 features an adjustable output voltage from  $1.25\text{V}$  to  $5.5\text{V}$ , using two external resistors connected as a voltage-divider to FB (Figure 3).

The output voltage is set by the following equation:

$$V_{OUT} = V_{FB} \left( 1 + \frac{R3}{R4} \right)$$

where typically  $V_{FB} = 1.257\text{V}$ . Choose  $R4 = 1.2\text{M}\Omega$  to optimize quiescent current, accuracy, and high-frequency power-supply rejection. To simplify resistor selection:

$$R3 = R4 \left( \frac{V_{OUT}}{V_{FB}} - 1 \right)$$

The total current through the external resistive feedback and load resistors should be greater than  $1\mu\text{A}$ . Since the  $V_{FB}$  tolerance is typically less than  $\pm 1.5\%$ , the output can be set using fixed resistors instead of trim pots.

### Power-Supply Rejection and Operation from Sources Other than Batteries

The MAX8880/MAX8881 are designed to deliver low-dropout voltages and low quiescent currents in battery-powered systems. Power-supply rejection is  $-66\text{dB}$  at low frequencies and rolls off with frequencies above  $100\text{Hz}$ . At high frequencies, the output capacitor is the major contributor to the rejection of power-supply noise (see Power-Supply Rejection Ratio vs. Frequency in the *Typical Operating Characteristics*).

When operating from sources other than batteries, improve supply-noise rejection and transient response by increasing the value of the input and output capacitors and by using passive filtering techniques.

The MAX8880/MAX8881 load-transient response graphs (see *Typical Operating Characteristics*) show the output response due to changing load current. Reduce overshoot by increasing the output capacitor's value up to  $10\mu\text{F}$  and by reducing its ESR.
