

32x32 Video Crosspoint

The ISL59532 is a 300MHz 32x32 Video Crosspoint Switch. Each input has an integrated DC-restore clamp and an input buffer. Each output has a fast On-Screen Display (OSD) switch (for inserting graphics or other video) and an output buffer. The switch is non-blocking, so any combination of inputs to outputs can be chosen, including one channel driving multiple outputs. The Broadcast Mode directs one input to all 32 outputs. The output buffers can be individually controlled through the SPI interface, the gain can be programmed to x1 or x2, and each output can be placed into a high impedance mode.

The ISL59532 offers a typical -3dB signal bandwidth of 300MHz. Differential gain of 0.025% and differential phase of 0.05°, along with 0.1dB flatness out to 50MHz, make the ISL59532 suitable for many video applications.

The switch matrix configuration and output buffer gain are programmed through an SPI/QSPI™-compatible three-wire serial interface. The ISL59532 interface is designed to facilitate both fast updates and initialization. On power-up, all outputs are high impedance to avoid output conflicts.

The ISL59532 is available in a 356 ball BGA package and specified over an extended -40°C to +85°C temperature range.

The single-supply ISL59532 can accommodate input signals from 0V to 3.5V and output voltages from 0V to 3.8V. Each input includes a clamp circuit that restores the input level to an externally applied reference in AC-coupled applications.

The ISL59533 is a fully differential input version of this device.

Features

- 32x32 non-blocking switch with buffered inputs and outputs
- 300MHz typical bandwidth
- 0.025%/0.05° dG/dP
- Output gain switchable x1 or x2 for each channel
- Individual outputs can be put in a high impedance state
- -90dB Isolation at 6MHz
- SPI digital interface
- Single +5V supply operation
- Pb-free plus anneal available (RoHS compliant)

Applications

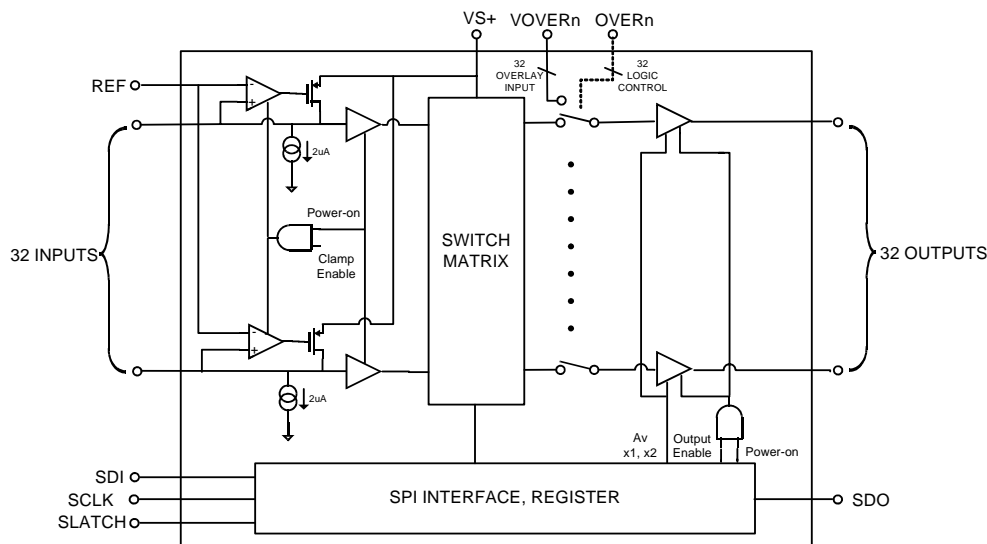

- Security camera switching
- RGB routing
- HDTV routing

Ordering Information

PART NUMBER	TAPE & REEL	PACKAGE (Pb-Free)	PKG. DWG. #
ISL59532IKEZ	-	356 Ld BGA	V356.27x27A

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

⊕ = NO BALLS

Balls labelled "NC" should be left unconnected - do not tie them to ground!
Balls with no labels may be tied to ground to slightly reduce thermal impedance.

Absolute Maximum Ratings ($T_A = 25^\circ\text{C}$)

Supply Voltage between V_S and GND 6.0V
 Maximum Continuous Output Current 40mA
 Ambient Operating Temperature -40°C to $+85^\circ\text{C}$
 Maximum Die Temperature $+125^\circ\text{C}$
 Storage Temperature -65°C to $+150^\circ\text{C}$

Maximum power supply (V_S) slew rate 1V/ μs
 ESD Classification
 Human Body Model 1500V
 Machine Model 100V

CAUTION: Stresses above those listed in "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

IMPORTANT NOTE: All parameters having Min/Max specifications are guaranteed. Typical values are for information purposes only. Unless otherwise noted, all tests are at the specified temperature and are pulsed tests, therefore: $T_J = T_C = T_A$

DC Electrical Specifications $V_S = 5\text{V}$, $R_L = 150\Omega$ unless otherwise noted.

PARAMETER	DESCRIPTION	CONDITION	MIN	TYP	MAX	UNIT
V_S	Power Supply Voltage		4.5		5.5	V
V_{SDO}	Power Supply for SDO output pin	Establishes serial data output high level	1.2		5.5	V
A_V	Gain	$A_V = 1$	0.98	1	1.02	V/V
		$A_V = 2$	1.96	2	2.04	V/V
GM	Gain Matching (to average of all other outputs)	$A_V = 1$	-1.5		+1.5	%
		$A_V = 2$	-1.5		+1.5	%
V_{IN}	Video Input Voltage Range	$A_V = 1$	0		3.5	V
V_{OUT}	Video Output Voltage Range	$A_V = 2$	0.1		3.8	V
I_B	Input Bias Current	Clamp function disabled (DC coupled inputs)	-10	-5	1	μA
		Clamp function enabled, $V_{IN} = V_{REF} + 0.5\text{V}$	0.5	2	10	μA
V_{OS}	Output Offset Voltage	$A_V = 1$	-20	8	35	mV
		$A_V = 2$	-100	-24	40	mV
I_{OUT}	Output Current	Sourcing, $R_L = 10\Omega$ to GND	60	108		mA
		Sinking, $R_L = 10\Omega$ to 2.5V	24	31		mA
PSRR	Power Supply Rejection Ratio	$A_V = 2$	50	70		dB
I_S	Supply Current	Enabled, all outputs enabled, no load current	560	640	720	mA
		Enabled, all outputs disabled, no load current	280	320	360	mA
		Disabled	1.2	1.8	2.4	mA

AC Electrical Specifications $V_S = 5\text{V}$, $R_L = 150\Omega$ unless otherwise noted.

PARAMETER	DESCRIPTION	CONDITION	MIN	TYP	MAX	UNIT
BW -3dB	3dB Bandwidth	$V_{OUT} = 200\text{mV}_{P-P}$, $A_V = 2$		300		MHz
BW 0.1dB	0.1dB Bandwidth	$V_{OUT} = 200\text{mV}_{P-P}$, $A_V = 2$		50		MHz

V _{REF}	M3	DC-restore clamp reference input. In an AC-coupled configuration (DC-Restore clamp enabled), the sync tip of composite video inputs will be restored to this level. Set to 0.3 to 0.7V for optimum performance. In an DC-coupled configuration (DC-Restore clamp disabled), this pin should be tied to ground. Never let the V_{REF} pin float! A floating VREF pin drifts high (and if the clamp function is enabled) will cause all of the outputs to simultaneously try to drive ~4V DC into their 150Ω loads.
SLATCH	J3	Serial Latch. Serial data is latched into ISL59532 on rising edge of SLATCH.
SCLK	K3	Serial data clock
SDI	L3	Serial data input
SDO	G3	Serial data output. Can be tied to SDI of another ISL59532 to enable daisy-chaining of multiple devices.
RESET	H3	Reset input. Pull high then low to reset device, but not needed in normal operation. Tie to ground in final application.
V _{SDO}	D3	Power supply for SDO pin. Tie to +5V for a 0 to 5V SDO output signal swing.
V _S		+5V power supply
GND		Ground
NC		No Connect - <i>Do not electrically connect to anything, including ground.</i>

Block Diagram

General Description

The ISL59532 is a 32x32 integrated video crosspoint switch matrix with input and output buffers and On-Screen Display (OSD) insertion. This device operates from a single +5V supply. Any output can be generated from any of the 32 input video signal sources, and each output can have OSD information inserted through a dedicated, fast 2:1 mux located before the output buffer. There is also a Broadcast mode allowing any one input to be broadcast to all 32 outputs. A DC restore clamp function enables the ISL59532 to AC-couple incoming video.

The ISL59532 offers a -3dB signal bandwidth of 300MHz. Differential gain and differential phase of 0.025% and 0.05° respectively, along with 0.1dB flatness out to 50MHz make this ideal for multiplexing composite NTSC and PAL signals. The switch matrix configuration and output buffer gain are programmed through an SPI/QSPI™-compatible, three-wire serial interface. The ISL59532 interface is designed to facilitate both fast initialization and configuration changes. On power-up, all outputs are initialized to the disabled state to avoid output conflicts in the user's system.

Digital Interface

The ISL59532 uses a serial interface to program the configuration registers. The serial interface uses three signals (SCLK, SDI, and SLATCH) for programming the ISL59532, while a fourth signal (SDO) enables optional

daisy-chaining of multiple devices. The serial clock can run at up to 5MHz (5Mbits/s).

Serial Interface

The ISL59532 is programmed through a simple serial interface. Data on the SDI (serial data input) pin is shifted into a 16-bit shift register on the rising edge of the SCLK (serial clock) signal. (This is continuously done regardless of the state of the SLATCH signal.) The LSB (bit 0) is loaded first and the MSB (bit 15) is loaded last (see the Serial Timing Diagram). After all 16 bits of data have been loaded into the shift register, the rising edge of SLATCH updates the internal registers.

While the ISL59532 has an SDO (Serial Data Out) pin, it does not have a register readback feature. The data on the SDO pin is an exact replica of the incoming data on the SDI pin, delayed by 15.5 SCLKs (an input bit is latched on the rising edge of SCLK, and is output on SDO on the falling edge of SCLK 15.5 SCLKs later). Multiple ISL59532's can be daisy-chained by connecting the SDO of one to the SDI of the other, with SCLK and SLATCH common to all the daisy-chained parts. After all the serial data is transmitted (16 bits * n devices = 16*n SCLKs), the rising edge of SLATCH will update the configuration registers of all n devices simultaneously.

The Serial Timing Diagram and Serial Timing Parameters table show the timing requirements for the serial interface.

Serial Timing Diagram

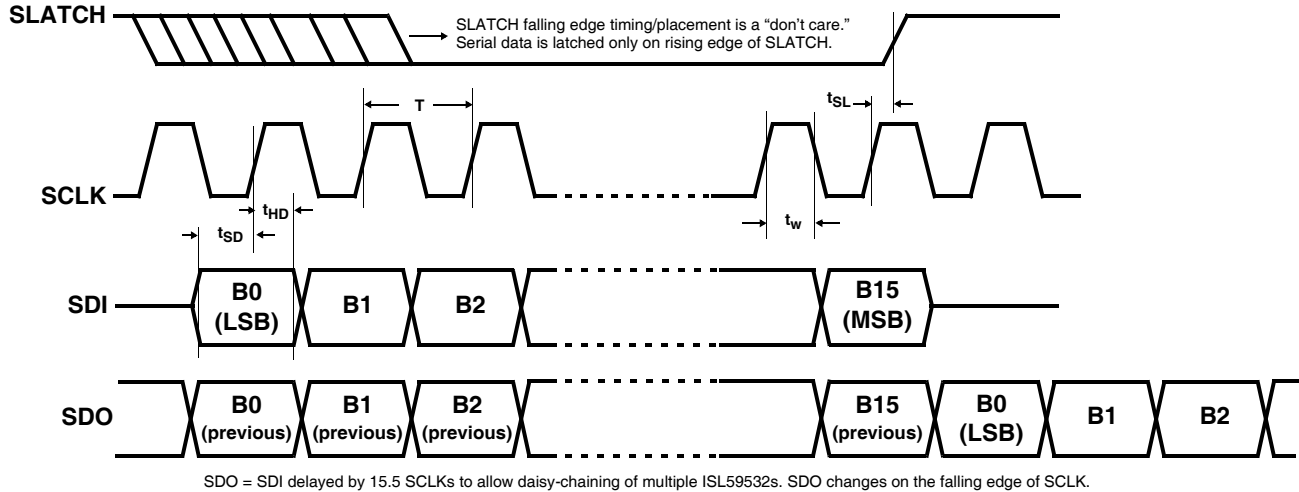

TABLE 1. SERIAL TIMING PARAMETERS

PARAMETER	RECOMMENDED OPERATING RANGE	DESCRIPTION
T	≥200ns	SCLK period
tw	0.50 * T	Clock Pulse Width
tSD	≥20ns	Data Setup Time
tHD	≥20ns	Data Hold Time
tSL	≥20ns	Final SCLK rising edge (latching B15) to SLATCH rising edge

Programming Model

The ISL59532 is configured by a series of 16 bit serial control words. The three MSBs (B15-13) of each serial word determine the basic command:

TABLE 2. COMMAND FORMAT

B15	B14	B13	COMMAND	NUMBER OF WRITES
0	0	0	INPUT/OUTPUT: Maps input channels to output channels	32 (1 channel per write)
0	0	1	OUTPUT ENABLE: Output enable for individual channels	4 (8 channels per write)
0	1	0	GAIN SET: Gain (x1 or x2) for each channel	4 (8 channels per write)
0	1	1	BROADCAST: Enables broadcast mode and selects the input channel to be broadcast to all output channels	1
1	1	1	CONTROL: Clamp on/off, operational/standby mode, and global output enable/disable	1

Mapping Inputs to Outputs

Inputs are mapped to their desired outputs using the input/output control word. Its format is:

TABLE 3. INPUT/OUTPUT WORD

B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
0	0	0	I ₄	I ₃	I ₂	I ₁	I ₀	-	-	-	O ₄	O ₃	O ₂	O ₁	O ₀

I₄:I₀ form the 5 bit word indicating the input channel (0 to 31), and O₄:O₀ determine the output channel which that input channel will map to. One input can be mapped to one or multiple outputs. To fully program the ISL59532, 32 INPUT/OUTPUT words must be transmitted - one for each input channel.

Enabling Outputs

The output enable control word is used to enable individual outputs. There are 32 channels to configure, so this is accomplished by writing 4 serial words, each controlling a bank of eight outputs at a time. The bank is selected by bits B9 and B8. The output enable control word format is:

TABLE 4. OUTPUT ENABLE FORMAT

B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
0	0	1	0	0	0	0	0	O ₇	O ₆	O ₅	O ₄	O ₃	O ₂	O ₁	O ₀
0	0	1	0	0	0	0	1	O ₁₅	O ₁₄	O ₁₃	O ₁₂	O ₁₁	O ₁₀	O ₉	O ₈
0	0	1	0	0	0	1	0	O ₂₃	O ₂₂	O ₂₁	O ₂₀	O ₁₉	O ₁₈	O ₁₇	O ₁₆
0	0	1	0	0	0	1	1	O ₃₁	O ₃₀	O ₂₉	O ₂₈	O ₂₇	O ₂₆	O ₂₅	O ₂₄

Setting the O_N bit = 0 tristates the output. Setting the O_N bit = 1 enables the output if the Global Output Enable bit is also set (the individual output enable bits are ANDed with the Global Output Enable bit before they are sent to the output stage).

Setting the Gain

The gain of each output may be set to x1 or x2 using the Gain Set word. It is in the same format as the output enable control word:

TABLE 5. GAIN SET FORMAT

B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
0	1	0	0	0	0	0	0	G ₇	G ₆	G ₅	G ₄	G ₃	G ₂	G ₁	G ₀
0	1	0	0	0	0	0	1	G ₁₅	G ₁₄	G ₁₃	G ₁₂	G ₁₁	G ₁₀	G ₉	G ₈
0	1	0	0	0	0	1	0	G ₂₃	G ₂₂	G ₂₁	G ₂₀	G ₁₉	G ₁₈	G ₁₇	G ₁₆
0	1	0	0	0	0	1	1	G ₃₁	G ₃₀	G ₂₉	G ₂₈	G ₂₇	G ₂₆	G ₂₅	G ₂₄

Set G_N = 0 for a gain of x1 or 1 for a gain of x2.

Broadcast Mode

The Broadcast Mode routes one input to all 32 outputs. The broadcast control word is:

TABLE 6. BROADCAST FORMAT

B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
0	1	1	I ₄	I ₃	I ₂	I ₁	I ₀	0	0	0	0	0	0	0	Enable Broadcast 0: Broadcast Mode Disabled 1: Broadcast Mode Enabled

I₄:I₀ form the 5 bit word indicating the input channel (0 to 31) to be sent to all 32 outputs. Set the Enable Broadcast bit (B0) = 1 to enable Broadcast Mode, or to 0 to disable Broadcast Mode. When Broadcast Mode is disabled, the previous channel assignments are restored.

Control Word

The ISL59532's power-on reset disables all outputs and places the part in a low-power standby mode. To enable the device, the following control word should be sent:

TABLE 7. CONTROL WORD FORMAT

B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
1	1	1	0	0	0	Clamp 0: Clamp Disabled 1: Clamp Enabled	0	0	0	0	0	0	0	Power 0: Standby 1: Operational	Global Output Enable 0: All outputs tristated 1: Individual Output Enable bits control outputs

The Clamp bit enables the input clamp function, forcing the AC-coupled signal's most negative point to be equal to V_{REF}.

Note: The Clamp bit turns the DC-Restore clamp function on or off for *all* channels - there is no DC-Restore on/off control for individual channels. The DC-Restore function only works with signals with sync tips (composite video). Signals that do not have sync tips (the Chroma/C signal in s-video and the Pb, Pr signals in Component video), will be severely distorted if run through a DC-Restore/clamp function.

For this reason, the ISL59532 must be in DC-coupled mode (Clamp Disabled) to be compatible with s-video and component video signals.

Bandwidth Considerations

Wide frequency response (high bandwidth) in a video system means better video resolution. Four sets of frequency response curves are shown in Figure 47. Depending on the switch configurations, and the routing (the path from the input to the output), bandwidth can vary between 100MHz and 350MHz. A short discussion of the trade-offs — including matrix configuration, output buffer gain selection, channel selection, and loading — follows.

FIGURE 47. FREQUENCY RESPONSE FOR VARIOUS MODES

In multiplexer mode, one input typically drives one output channel, while in broadcast mode, one input drives all 32 outputs. As the number of outputs driven increases, the parasitic loading on that input increases. Broadcast Mode is the worst-case, where the capacitance of all 32 channels loads one input, reducing the overall bandwidth. In addition, due to internal device compensation, an output buffer gain of x2 has higher bandwidth than a gain of x1. Therefore, the highest bandwidth configuration is multiplexer mode (with each input mapped to only one output) and an output buffer gain of x2.

The relative locations of the input and output channels also have significant impact on the device bandwidth (due to the layout of the ISL59530 silicon). When the input and output channels are further away, there are additional parasitics as a result of the additional routing, resulting in lower bandwidth.

The bandwidth does not change significantly with resistive loading as shown in the typical performance curves. However several of the curves demonstrate that frequency response is sensitive to capacitance loading. This is most significant when laying out the PCB. If the PCB trace length between the output of the crosspoint switch and the back-termination resistor is not minimized, the additional parasitic capacitance will result in some peaking and eventually a reduction in overall bandwidth.

Linear Operating Region

In addition to bandwidth optimization, to get the best linearity the ISL59532 should be configured to operate in its most linear operating region. Figure 48 shows the differential gain curve. The ISL59532 is a single supply 5V design with its most linear region between 0.1 and 2V. This range is fine for most video signals whose nominal signal amplitude is 1V. The most negative input level (the sync tip for composite video) should be maintained at 0.3V or above for best operation.

FIGURE 48. DIFFERENTIAL GAIN RESPONSE

In a DC-coupled application, it is the system designer's responsibility to ensure that the video signal is always in the optimum range.

When AC coupling, the ISL59532's DC restore function automatically adjusts the DC level so that the most negative portion of the video is always equal to V_{REF} .

A discussion of the benefits of the DC-restored system begins by understanding the block diagram of a typical DC-restore circuit (Figure 49). It consists of 4 sections: an AC coupling (DC blocking) capacitor at the input, an opamp, a FET switch, and a current source. In the absence of an input signal, R_{TERM} pulls the input node to ground. The $2\mu A$ current source slowly drains the input capacitor of charge, slowly lowering V_{OUT} . However when V_{OUT} goes below V_{REF} , Q1 turns on, sourcing current into the capacitor until V_{OUT} is equal to V_{REF} , at which point Q1 will turn off. So with no V_{IN} signal, the voltage at the noninverting input of the opamp will settle to approximately V_{REF} , with Q1 sourcing the same $2\mu A$ as the current source.

FIGURE 49. DC RESTORE BLOCK DIAGRAM

When a video signal is applied to V_{IN} , the most negative signal will be the sync tip. If the sync tip goes below V_{REF} , Q1 will turn on and quickly source enough current into C_{IN} so that the sync tip is forced to be equal to V_{REF} . After the sync tip, the video jumps up by 300mV or more, so V_{OUT} becomes $\gg V_{REF}$, so Q1 will not turn on for the rest of the video line. However the 2µA current source continues to slowly discharge C_{IN} , so that by the end of the video line, the next sync tip will again be slightly below V_{REF} , forcing Q1 to source some current into C1 to make $V_{OUT} = V_{REF}$ during the sync tip.

This is how the video is “DC-restored” after being AC coupled into the ISL59532. The sync tip voltage will be equal to V_{REF} , on the right side of C_{IN} , regardless of the DC level of the video on the left side of C_{IN} . Due to various sources of offset in the actual clamp function, the actual sync tip level is typically about 75mV higher than V_{REF} (for $V_{REF} = 0.5V$).

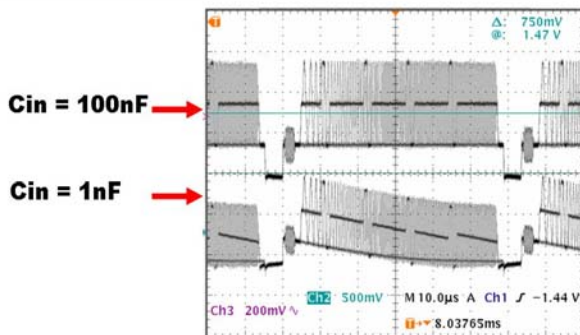

FIGURE 50. DC RESTORE VIDEO WAVEFORMS

It is important to choose the correct value for C_{IN} . Too small a value will generate too much droop, and the image will be visibly darker on the right than on the left. A C_{IN} value that is too large may cause the clamp to fail to converge. The droop rate (dV/dt) is $I_{PULLDOWN}/C_{IN}$ volts/second. In general, the droop voltage should be limited to <1 IRE over a period of one line of video; so for 1 IRE = 7mV, $I_B = 10\mu A$ maximum, and an NTSC waveform we will set $C_{IN} > 10\mu A * 60\mu s / 7mV = 0.086\mu F$. Figure 50 shows the result of $C_{IN} = 0.1\mu F$

delivering acceptable droop and $C_{IN} = 0.001\mu F$ producing excessive droop

When the clamp function is disabled in the CONTROL register (Clamp = 0) to allow DC-coupled operation, the I_{CLAMP} current sinks/sources are disabled and the input passes through the DC Restore block unaffected. In this application V_{REF} may be tied to GND.

Overlay Operation

The ISL59532 features an overlay feature, that allows an external video signal or DC level to be inserted in place of that output channel's video. When the $OVER_N$ signal is taken high, the output signal on the OUT_N pin is replaced with the signal on the $VOVER_N$ pin.

There are several ways the overlay feature can be used. Toggling the $OVER_N$ signal at the frame rate or slower will replace the video frame(s) on the OUT_N pin with the video supplied on the $VOVER_N$ pin.

Another option (for OSD displays, for example), is to put a DC level on the $VOVER_N$ line and toggle the $OVER_N$ signal at the pixel rate to create a monochrome image “overlaid” on channel N's output signal.

Finally, by enabling the $OVER_N$ signal for some portion of each line over a certain amount of lines, a picture-in-picture function can be constructed.

It's important to note that the overlay inputs do not have the DC Restore function previously described - the overlay signal is DC coupled into the output. It is the system designer's responsibility to ensure that the video levels are in the ISL59532's linear region and matching the output channel's offset and amplitude. One easy way to do this is to run the video to be overlaid through one of the ISL59532's unused channels and then into the $VOVER_N$ input.

The $OVER_N$ pins all have weak pulldowns, so if they are unused, they can either be left unconnected or tied to GND.

Power Dissipation and Thermal Resistance

With a large number of switches, it is possible to exceed the 150°C absolute maximum junction temperature under certain load conditions. Therefore, it is important to calculate the maximum junction temperature for an application to determine if load conditions or package types need to be modified to assure operation of the crosspoint switch in a safe operating area.

The maximum power dissipation allowed in a package is determined according to:

$$PD_{MAX} = \frac{T_{JMAX} - T_{AMAX}}{\Theta_{JA}}$$

Where:

- T_{JMAX} = Maximum junction temperature = 125°C
- T_{AMAX} = Maximum ambient temperature = 85°C
- θ_{JA} = Thermal resistance of the package

The maximum power dissipation actually produced by an IC is the total quiescent supply current times the total power supply voltage, plus the power in the IC due to the load, or:

$$PD_{MAX} = V_S \times I_{SMAX} + \sum_{i=1}^n (V_S - V_{OUTi}) \times \frac{V_{OUTi}}{R_{Li}}$$

Where:

- V_S = Supply voltage = 5V
- I_{SMAX} = Maximum quiescent supply current = 700mA
- V_{OUT} = Maximum output voltage of the application = 2V
- R_{LOAD} = Load resistance tied to ground = 150
- n = 1 to 32 channels

$$PD_{MAX} = V_S \times I_{SMAX} + \sum_{i=1}^n (V_S - V_{OUTi}) \times \frac{V_{OUTi}}{R_{Li}} = 4.8W$$

The required θ_{JA} to dissipate 4.8W is:

$$\theta_{JA} = \frac{T_{JMAX} - T_{AMAX}}{PD_{MAX}} = 8.33(^{\circ}C/W)$$

Table 8 shows θ_{JA} thermal resistance results with a Wakefield heatsink and without heatsink and various airflow. At the thermal resistance equation shows, the required thermal resistance depends on the maximum ambient temperature.

TABLE 8. θ_{JA} THERMAL RESISTANCE [$^{\circ}C/W$]

Airflow [LFM]	0	250	500	750
No Heatsink	18	14.3	13.0	12.6
Wakefield 658-25AB Heatsink	16.0	7.0	6.0	4.7
